```

1 Introduction

In this practice, we will work on fitting different volatility models (ARCH and GARCH). We will also focus on discussing the validation and selection of the model. As done in previous practices, each student group must follow the practice script below, performing the necessary calculations and graphs in the R environment. The obtained results and answers to the questions should be compiled into a document containing your solution, created, for example, in R Markdown or Microsoft Word. Please make sure to include your full names and group number at the beginning of the document. Submit the questionnaire solution in PDF format by uploading it to the platform under the corresponding task section before the deadline.

In this questionnaire, we will work with the following time series:

- KO: The Coca-Cola Company (KO) stock (NYSE)

You can download the data using this code:

```
library(quantmod)   # quant finc modeling and trading framework
getSymbols("KO")
```

```
[1] "KO"
```

2 Questions

2.1 Download Data

Task: Download the time series. You may work with the complete dataset (from 2007 to the most recent trading session).

Solution

```
cat('column names:', names(KO), '\n\n')  # columns
```

```
column names: KO.Open KO.High KO.Low KO.Close KO.Volume KO.Adjusted
```

```
summary(KO)                             # quick summary stats
```

```
     Index               KO.Open          KO.High          KO.Low

```

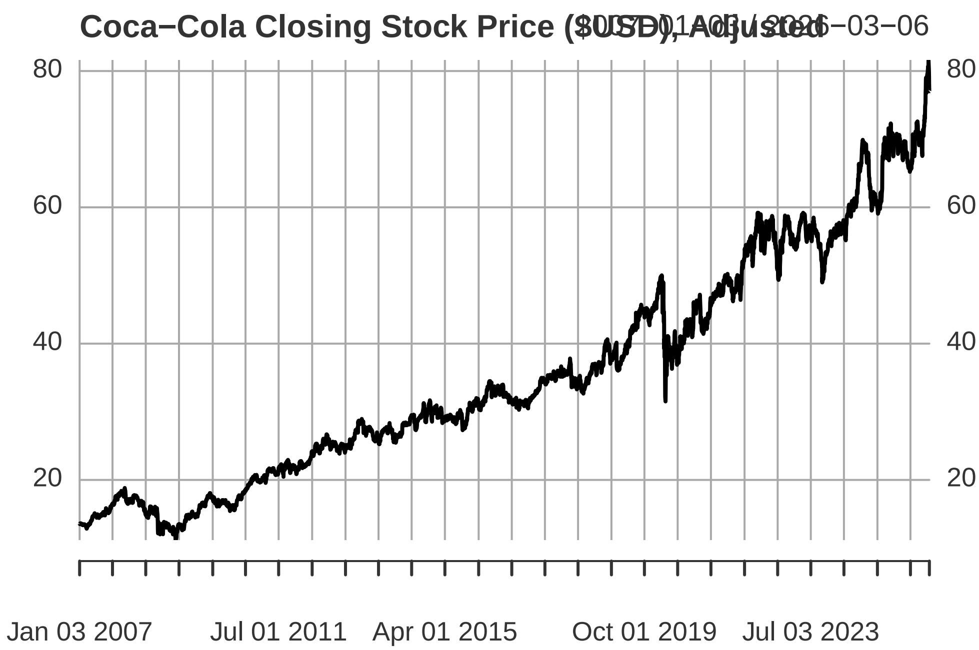
```
chartSeries(KO)                         # financial chart
```

2.2 Graphical Representation

Task: Create a graphical representation of the time series using the Adjusted Closing Price.

Solution

```
plot(KO$KO.Adjusted,
     main = "Coca-Cola Closing Stock Price ($USD), Adjusted")
```



2.3 Compute Log-Returns

Task: Compute the log-returns of the series. It is not necessary to model the mean (e.g., using an ARIMA model).

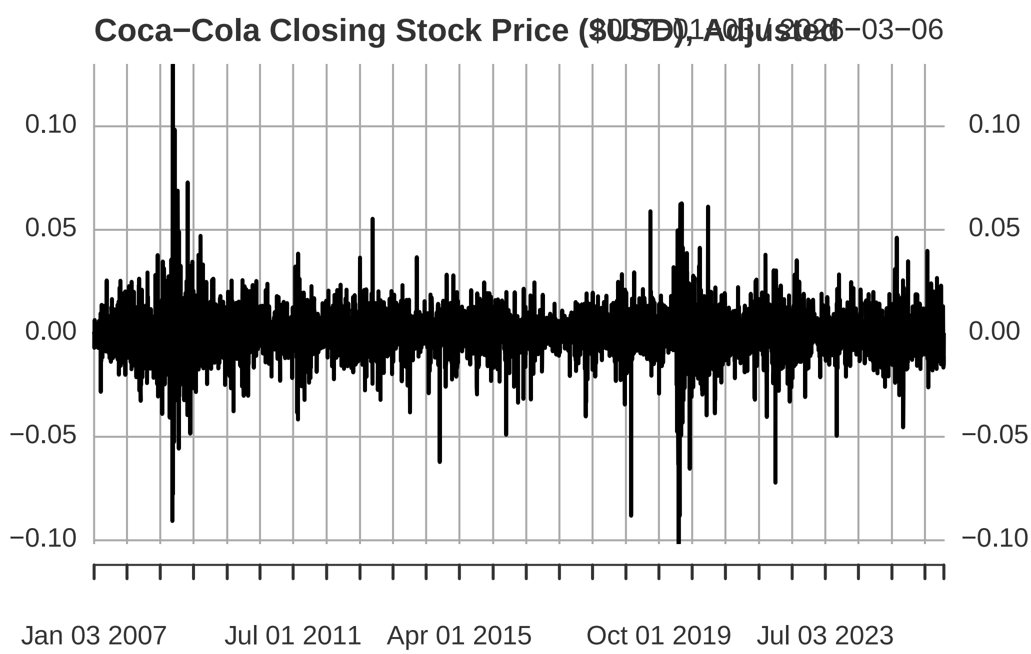
Solution

```
# returns: can do this directly using fQuant library
KO$log_Adjusted <- dailyReturn(KO$KO.Adjusted,
                              type = "log")

# sanity check
head(KO$log_Adjusted)
```

```
           log_Adjusted
2007-01-03  0.0000000000
2007-01-04  0.0004118395
2007-01-05 -0.0070204185
2007-01-08  0.0064024905
2007-01-09  0.0008230482
2007-01-10  0.0014397037
```

```
# plot
plot(KO$log_Adjusted,
     main = "Coca-Cola Closing Stock Price ($USD), Adjusted") # looks stationary -- good
```



2.4 Model Fitting

Task: Using the fGarch package, fit the following models to the log-returns: an ARCH(1) model, an ARCH(3) model, and a GARCH(1,1) model.

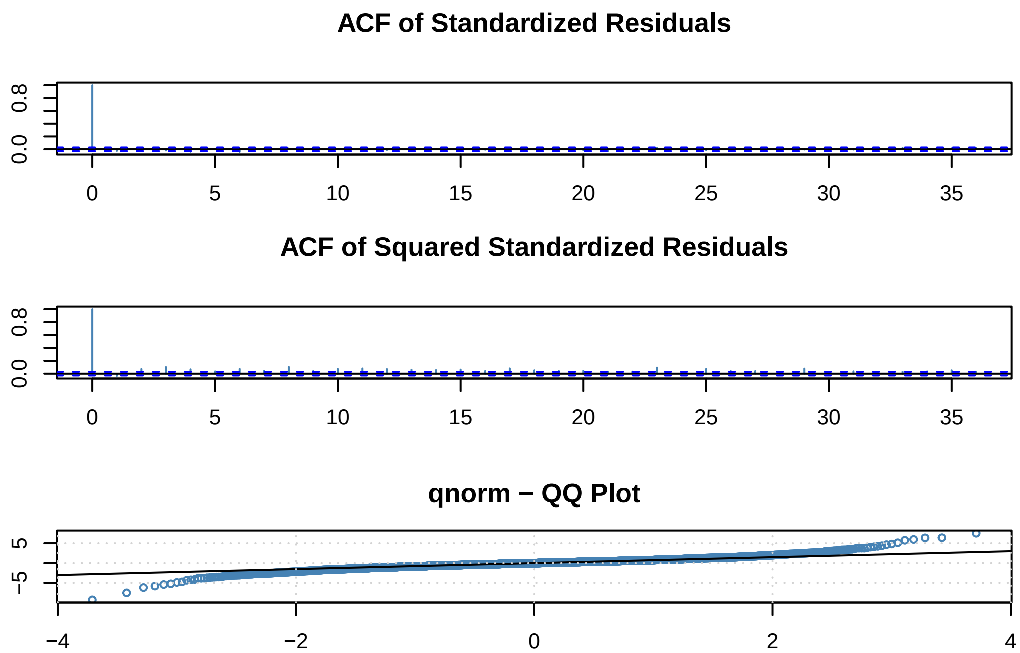
Solution

```r
library(fGarch)
```

2.4.1 ARCH(1)

```r
# fit a arch(1) [~garch(1,0)] model
arch_1_md <- garchFit(formula = ~ garch(1, 0),
                data = KO$log_Adjusted,
                trace = FALSE)

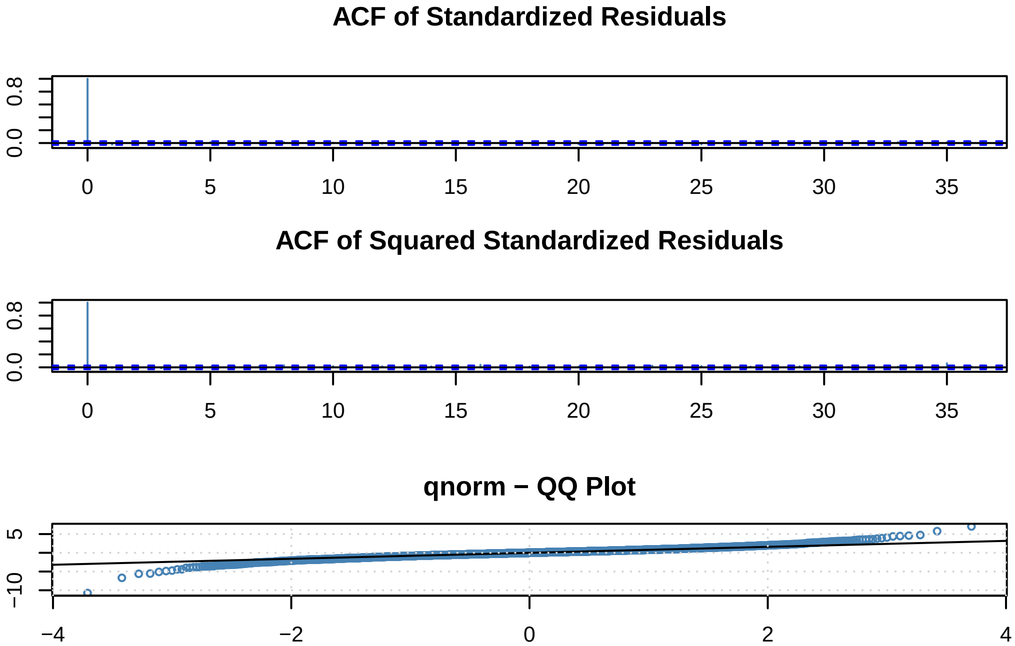
par(mar=c(3,3,3,1))
tsdiag(arch_1_md)
```



2.4.2 ARCH(3)

```r
# fit a arch(3) [~garch(3,0)] model
arch_3_md <- garchFit(formula = ~ garch(3, 0),
                data = KO$log_Adjusted,
                trace = FALSE)

par(mar=c(3,3,3,1))
tsdiag(arch_3_md)
```

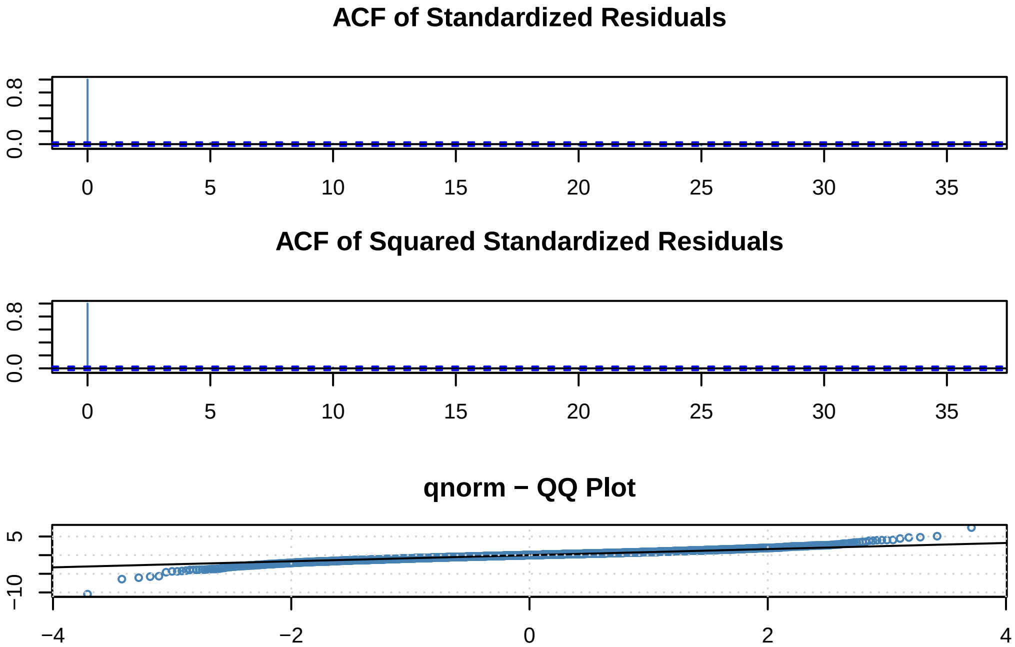


We see that [...]

2.4.3 GARCH(1,1)

```
# fit a garch(1,1) model
garch_11_md <- garchFit(formula = ~ garch(1, 1),
                data = KO$log_Adjusted,
                trace = FALSE)

par(mar=c(3,3,3,1))
tsdiag(garch_11_md)
```



We see that […]

2.5 Fitted Model Expressions

Task: Write the expression of each fitted model.

Solution

Note that the ARCH(p) model takes the form:

$$\text{Mean Equation: } \quad X_t = \mu + Z_t \text{Variance Equation: } \quad \sigma_t^2 = \alpha_0 + \alpha_1 Z_{t-1}^2 + \alpha_2 Z_{t-2}^2 ... \alpha_p Z_{t-p}^2$$

With the random error Z_t being defined as:

$$Z_t = \sqrt{\sigma_t^2} \varepsilon_t, \quad \varepsilon_t \sim WN(0,1)$$

2.5.1 ARCH(1)

```r
sum1 <- summary(arch_1_md)
```

```
